

Background & Motivation

- Information asymmetry is a fundamental source of market inefficiency, giving rise to adverse selection and moral hazard and leading to persistent welfare losses in principal-agent relationships. Traditional mechanisms—such as signaling, screening, and monitoring—are often costly, coarse, and vulnerable to strategic manipulation. Generative AI fundamentally alters this environment by producing high-precision, multi-dimensional, and continuously updated signals about agent types and actions. By lowering information acquisition and monitoring costs, AI reshapes the informational foundation of contract design rather than merely improving existing mechanisms.

- Can generative AI-enhanced signals push principal-agent equilibria toward the first-best benchmark?
- How do the resulting efficiency gains, rent redistribution, and welfare effects vary across different market structures (competitive, oligopolistic, and monopolistic)?

Theoretical Framework

Generative AI in Principal-Agent Relationships

Traditional Principal-Agent Relationship with Information Asymmetry

Principal
 $U_P = V(e, \theta) - w$
 Limited Information

Information Asymmetry
 Adverse Selection
 (Hidden Type θ)
 Moral Hazard
 (Hidden Effort e)

Agent
 $U_A = w - c(e, \theta)$
 Private Information

Generative AI Signal Enhancement

Type Signal Generation
 $s_\theta = \theta + \varepsilon_\theta$
 $\varepsilon_\theta \sim N(0, \sigma^2_\theta)$
 As $\sigma^2_\theta \rightarrow 0$:
 Precise Type Assessment

Bayesian Signal Processing
 $f(\theta, e | s_\theta, s_e) \propto f(s_\theta | s_e, \theta) f(\theta) f(e)$
 Principal updates beliefs about agent's type and effort based on AI signals

AI-Enhanced Contract Design
 $w(s_\theta, s_e)$ optimized using signal information

Effort Signal Generation
 $s_e = e + \varepsilon_e$
 $\varepsilon_e \sim N(0, \sigma^2_e)$
 As $\sigma^2_e \rightarrow 0$:
 Precise Effort Monitoring

Improved Contractual Outcomes

Reduced Adverse Selection

- Better type identification
- Optimal agent matching
- Reduced screening costs

Reduced Moral Hazard

- Better effort verification
- Aligned incentives
- Reduced monitoring costs

Welfare Improvements

- Approaching first-best
- Reduced information rents
- Enhanced market efficiency

Bayesian Updating Process

Principal Learning Agent Type Over Time Through Signal Accumulation

Signal Precision:
 $\varepsilon_\theta \sim N(0, \sigma^2_\theta)$
 where $\sigma^2_\theta \propto 1/t$

High Uncertainty $\text{Var}(\theta) = \sigma^2_\theta$

Reduced Uncertainty $\text{Var}(\theta|s_1) < \sigma^2_\theta$

Further Reduced Uncertainty $\text{Var}(\theta|s_2) < \text{Var}(\theta|s_1)$

Increasingly Concentrated Distribution

Narrower Distribution

Near-Perfect Knowledge

Very Low Variance

Posterior Variance:
 $\text{Var}(\theta|s_{1:t}) = \frac{1}{t/\sigma^2_\theta + (t-1)/\sigma^2_\theta} \text{Var}(\theta|s_{1:t-1})$

Posterior 1 $f(\theta|s_1)$

Posterior 2 $f(\theta|s_2)$

Posterior 3 $f(\theta|s_3)$

Posterior 4 $f(\theta|s_4)$

Posterior 5 $f(\theta|s_5)$

Posterior Variance Reduction

$f(\theta|s_{1:t}) \propto f(\theta) \times \prod_{i=1}^t f(s_i|\theta)$

Competitive Markets

Strongest Benefits

Oligopolistic Markets

Moderate Benefits

Monopolistic Markets

Limited Benefits

Experiments & Key Findings

Effort Level Distribution

Y-axis: Effort Level (0.0 to 1.0). X-axis: Group and Agent Type (With AI - Agent, With AI - Principal, Without AI - Agent, Without AI - Principal).

Social Welfare Distribution

Y-axis: Social Welfare (0 to 14). X-axis: Group and Agent Type (With AI - Agent, With AI - Principal, Without AI - Agent, Without AI - Principal).

Agent Utility vs Principal Profit

Y-axis: Value (0 to 10). X-axis: Group and Agent Type (With AI - Agent, With AI - Principal, Without AI - Agent, Without AI - Principal).

Contract Parameters vs Signal Quality

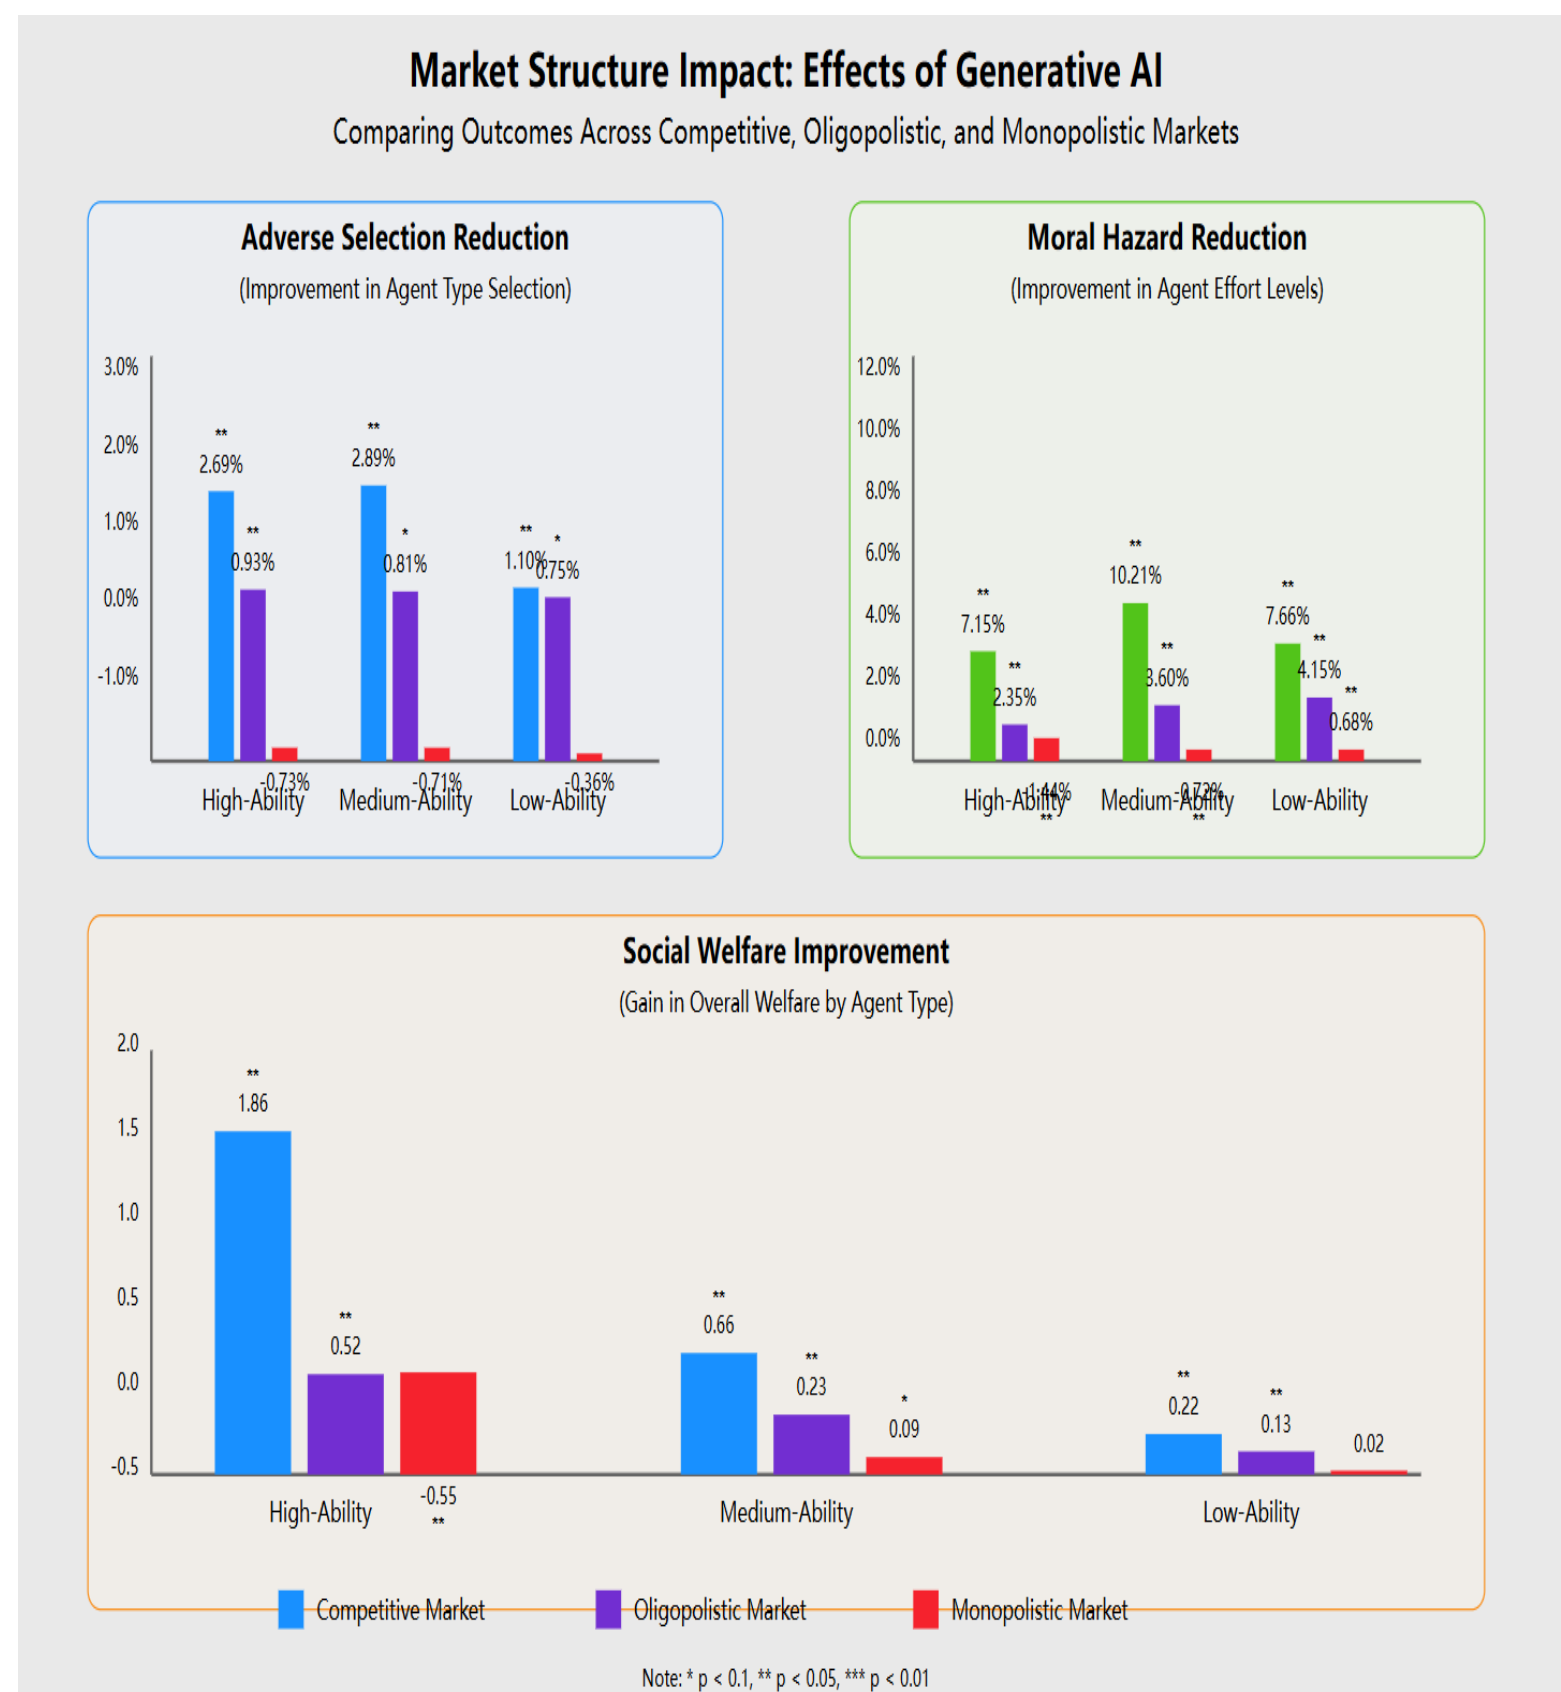

Y-axis: Performance Coefficient (0.65 to 1.00). X-axis: Signal Quality (0.00 to 1.00). Color scale: Agent Ability (0.3 to 0.9).

Welfare Analysis

Y-axis: Value (0 to 4). X-axis: With AI, Without AI. Legend: agent_utility (red), principal_profit (blue).

Social Welfare vs Agent Ability

Y-axis: Social Welfare (0 to 14). X-axis: Agent Ability (0.2 to 1.0). Legend: With AI (red line), Without AI (blue line).

- ## Policy Implication And Conclusion

- The results highlight the need for a policy framework that governs generative AI as an information infrastructure rather than merely a contractual tool. Transparency and signal certification are essential to ensure that AI-generated signals are accurate, auditable, and non-discriminatory. Data portability and fair competition rules can mitigate information concentration and prevent dominant firms from leveraging superior signals to entrench market power. At the same time, innovation subsidies and public support for AI R&D are necessary to sustain continuous improvements in signal quality, particularly in competitive markets where private incentives to invest may weaken.

- Overall, generative AI fundamentally reshapes the information structure underlying principal-agent relationships, not just the form of contracts. While efficiency gains from improved signals are substantial, their distributional consequences depend critically on market power. Effective AI governance must therefore be explicitly market-structure-aware, balancing efficiency, innovation, and equity.
